WHY WE BUILT THIS

Most revision fails for the same reason.

Re-reading notes and redoing familiar questions feels productive. It is not, because it never touches the dot-points that are actually costing you marks.

So we went through four years of real SACE Stage 2 papers, subject by subject, and mapped every question back to the exact dot-point it tested. The same handful of points show up, year after year, as the place students lose marks they should have kept.

We call the method **Mark-Loss Mapping**. This document is fourteen of those points: what the dot-point is, what the error actually looks like, and how to fix it before it costs you marks in November.

INSIDE THIS GUIDE

Chemistry	4 points · p.4
Physics	3 points · p.5
Biology	3 points · p.6
What to do next	p.7

4 dot-points that cost the most marks.

1 Chain rule inside a quotient

Students apply the chain rule correctly on its own, then drop it or misapply it the moment it is nested inside a quotient rule differentiation. The error is not understanding, it is tracking two rules in the same step.

2 Confidence interval interpretation

Across multiple simulated intervals, students describe what a single CI means rather than what "95% of intervals constructed this way" means. This distinction is tested almost every year and is rarely explained clearly at school.

3 Integration as accumulation

Applying integration to go from a rate function to a total accumulated quantity is mechanically simple but conceptually skipped: students integrate correctly but misinterpret what the resulting number represents in context.

4 Optimisation with a restricted domain

Students find the correct critical point but forget to check it against the domain restriction stated in the question, and lose marks on an otherwise fully correct solution.

4 dot-points that cost the most marks.

1 Kc with mismatched stoichiometric coefficients

Students set up the equilibrium expression correctly but forget to raise concentrations to the power of their coefficients, especially when coefficients are not 1. A small error, but it invalidates the whole calculation.

2 Faraday's law calculations

Electrolysis questions combine charge, moles of electrons and moles of product in one calculation. Students frequently substitute the wrong number of electrons transferred per mole of product, especially for multivalent ions.

3 AAS vs emission spectroscopy confusion

Atomic absorption and emission spectroscopy are taught close together and students frequently mix up which technique measures which phenomenon under exam pressure, costing marks on straightforward identification questions.

4 Multi-step synthesis reagents and conditions

Students can usually name the product of a multi-step organic synthesis but lose marks on the specific reagents and conditions (catalyst, temperature, solvent) required at each individual step.

3 dot-points that cost the most marks.

1 Projectile motion (deceptively easy)

Widely regarded as an "easy" topic, which is exactly why it costs so many marks: students skip careful component resolution and sign conventions because the topic feels familiar, and small setup errors compound through the whole solution.

2 Photoelectric effect graph analysis

Reading the work function and stopping voltage correctly off a frequency-vs-kinetic-energy graph is a common multi-mark question, and students frequently misread the intercepts or the gradient's physical meaning.

3 Cyclotron and combined force problems

Questions combining magnetic force and circular motion require students to correctly identify which force provides centripetal force, and this step is frequently skipped or assumed rather than justified, costing method marks even when the final answer is correct.

3 dot-points that cost the most marks.

1 Codon table translation (multi-step)

Translating a DNA sequence through mRNA to an amino acid sequence involves several sequential steps, and a single early error (like missing the reading frame) compounds through the rest of the answer.

2 Locating respiration stages correctly

Students can usually describe what happens in glycolysis, the Krebs cycle and the electron transport chain, but frequently misplace where each stage occurs in the cell, costing marks on location-based exam questions.

3 Meiosis vs mitosis and feedback loop steps

Students confuse where meiosis and mitosis diverge, and separately, tend to skip a step when describing a negative feedback loop under time pressure. Both cost marks on otherwise well-understood content.

WHAT TO DO NEXT

Knowing the gap is not the same as closing it.

This guide names 14 of the dot-points that cost the most marks. Our SACE Stage 2 Exam Crash Course is built entirely around this method: six two-hour sessions per subject, weighted to the points that matter most, finishing with a full mock exam marked and returned within 48 hours.

SACE Exam Crash Course

- ✓ 28 September to 10 October, in person in Adelaide
- ✓ Mathematical Methods · Chemistry · Physics · Biology
- ✓ Taught by tutors who sat these exact papers, several are current medical students
- ✓ A TopMark textbook included for every subject
- ✓ From \$20 per hour of teaching · early bird pricing until 6 September
